

Week 5 - Topic 1: Complex Data Types (Records, Enumerations)

Complex Data Types

This lecture we start by looking at **programmer** created Data Types:

1. Records/Classes
2. Enumerations

Versus Primitive Data Types

We have been using '**primitive**' data types which are **basic** types that come with the language Ruby (and most other languages).

These primitive/basic data types are the essential ones you need to create more complex data types.

What are the primitive data types we have been using so far?

Programmer Created Data Types

- Also known as '**custom**' data types.
- These are created to represent the entities you are modelling in your program.
- Each program is a model, or abstraction, of some aspects of the real world.
- As an abstraction, some details are left out, others are specifically included for the purpose of the model.

Complex Data Type Example

Consider a student.

- What attributes does a student have?

Complex Data Type Example II

- What student attributes would be included in a student administration system for a university?

Example Student Record (Data Dictionary)

Student Information		Academic Performance		Administrative Data	
Field Name	Data Type	Field Name	Data Type	Field Name	Data Type
Student ID	Integer	Math Score	Float	Enrollment Date	Date
First Name	String	Science Score	Float	Grade Level	String
Last Name	String	Reading Score	Float	School Year	String
Age	Integer	Writing Score	Float	Teacher ID	Integer
Gender	String	Average Score	Float	Classroom	String
Address	String	Attendance Rate	Float	Subject	String
City	String	Discipline Score	Float	Test Date	Date
State	String	Project Score	Float	Score Range	String
Zip	String	Portfolio Score	Float	Feedback	String
Phone	String	Peer Review	String	Comments	Text
Email	String	Self-Reflection	Text	Next Steps	Text

Date complex data type

- Some complex data types are not 'custom' in the sense that the application programmer needs to create them.
- Some complex data types are in libraries provided with or for the language.
Eg: Date ([which exists already for Ruby](#))
- If you were to write this yourself you might start with a record that looks as follows:

- This is an improvement on one long integer.

Using Classes and structs to Represent Complex Data Types

In Ruby we use **classes** to represent records such as the Student and Date records above.

▶ Run

RUBY

```
1 class Date
2   attr_accessor :day, :month, :year
3 end
```

In C we use structs which would look as follows:

▶ Run

C

```
1 typedef struct Date {
2   int day;
3   int month;
4   int year;
5 } Date;
6
7 int main(){
8   Date d;
9   d.day = 31;
10  d.month = 12;
11  d.year = 2019;
12 }
```

Each of these has three attributes (day, month, year).

Ruby also offers a form of struct:

▶ Run

RUBY

```
1 Student = Struct.new(:name, :id, :email, :course)
2
3 s = Student.new("Sam", "0320", "sam@uni.com.au")
4
5 puts "Name: " + s.name
6 puts "Id: " + s.id
7 puts "Email: " + s.email
```

Type/Token Distinction

- A class (or record or struct) represents a **type**.
- To allocate memory we need to create a **token**.
- We need to create an instance of the type.

Eg for Ruby:

```
date = Date.new()
```

- And for C:

```
Date date;
```

Using complex data types

Once we create an instance (token) of a complex data type, we need to initialize its field/attribute values (which we should do with all variables):

For our Date class (not the standard Ruby one):

▶ Run

RUBY

⌵

```
1 class Date
2   attr_accessor :day, :month, :year
3 end
4
5 date = Date.new()
6 date.day = 31
7 date.month = 12
8 date.year = 2019
9
10 puts "Date is #{date.day}-#{date.month}-#{date.year}"
11
12
```

And for C:

▶ Run

C

⌵

```
1 #include <stdio.h>
2
3 typedef struct Date {
4   int day;
5   int month;
6   int year;
7 } Date;
8
9 int main(){
10   Date d;
11   d.day = 31;
12   d.month = 12;
13   d.year = 2019;
14
```

Initialising Complex Data Types

In Ruby we can create a block of code to initialise the fields/attributes Eg for Ruby:

▶ Run

RUBY

```
1 class Date
2   attr_accessor :day, :month, :year
3
4   def initialize(day, month, year)
5     @day = day
6     @month = month
7     @year = year
8   end
9 end
10
11 date = Date.new(31, 12, 2019)
12
13
```

Nested Complex Data Types

A complex data type can have fields/members/attributes that are also complex data types:

▶ Run

RUBY

```
1 class Date
2   attr_accessor :day, :month, :year
3
4   def initialize(day, month, year)
5     @day = day
6     @month = month
7     @year = year
8   end
9 end
10
11 class Booking
12   attr_accessor :room, :date, :time
13
14   def initialize(room, date, time)
```

Enumerations

- Enumerations are a custom data type that holds constant values.
- Enumerations simply assign meaningful names to a set of integers.
- Eg: to Represent different Genres of music we could use 0, 1, 2, 3 etc. Or we could create an enumeration as follows:

▶ Run RUBY

```
1 module Genre
2   Pop, Classic, Jazz, Rock = *0..3
3 end
4
```

Pop = 0, Classic = 1, Jazz = 2 and Rock = 3.

In C, this would be:

▶ Run C

```
1 enum genre_names {Pop, Classic, Jazz, Rock};
2
3 int main(){
4 }
5
```

Example Enumeration

An enumeration you have already seen is one for the Z order of objects you draw on the screen in Gosu.

This substitutes 0 for BACKGROUND, 1 for PLAYER and 2 for UI.

▶ Run

RUBY

```
1 module ZOrder
2   BACKGROUND, PLAYER, UI = *0..2
3 end
```

Summary

Terminology:

- Primitive data types
- Complex Data Types
- Custom Data Types
- Enumerations
- Records
- Classes

Types Quiz

Which of the following statements are true:

- ☐ In Ruby we can represent complex types using classes
- ☐ In Ruby we can represent complex types using structs
- ☐ In Ruby we can represent custom types using modules
- ☐ In Ruby complex types can be components of other complex types
- ☐ Once you define a type you can assign values to the fields

Track File Handling Task

Lets look at how to solve the track reading task.

Types Supplement
